

AN ANNOTATED LIST OF THE MIRIDAE (HETEROPTERA) FOUND
IN THE YAZOO-MISSISSIPPI DELTA AND ASSOCIATED
AREAS IN ARKANSAS AND LOUISIANA

Abstract.—A list of the Miridae found in the Yazoo-Mississippi Delta and in associated areas in Arkansas and Louisiana is compiled from sweepnet, beating net, and black light trap samples taken from September 1981 through October 1982, and during May 1983. A total of 107 species representing 47 genera are reported. Thirty-nine species are considered new state records for Mississippi, 10 for Louisiana, and 5 for Arkansas. Months of collection, hosts, and methods of collection are given for each species studied.

The plant bug family Miridae is the largest and most diverse family found in the Hemiptera-Heteroptera. Most species are phytophagous, although an increasingly large number of species are known to be predatory. The best sources for information on the distribution and life cycles of species occurring in the eastern United States are the works of Blatchley (1926) and Knight (1923, 1941). In the Southeast, species of Miridae have been listed from Florida (Frost, 1964, 1966, 1969, and 1975), Georgia (Henry and Smith, 1979), Louisiana and Mississippi (Khalaf, 1971), North Carolina (Brimley, 1938; Wray, 1950 and 1967), and West Virginia (Wheeler et al., 1983).

The mirid species composition of the Yazoo-Mississippi Delta (Fig. 1) is largely unrecorded, with the exception of several crop species. The Delta, one of ten physiographic regions in Mississippi, is drained by several streams that empty into the Yazoo River that in turn empties into the Mississippi River near Vicksburg, MS. It is one of the most fertile bodies of land in the world (Bennett, 1921), and most of the land has been cleared of its native vegetation for crop production. The forests that remain are mostly restricted to state and national parks and the area found between the Mississippi River and its flood levees. Areas found along drainage ditches and between the ditches and cultivated land contain many of the species of woody and herbaceous vascular plants found in the Delta. The vascular flora of the Delta differed from that of surrounding areas by lacking at least 28 native species of trees, although many now have been introduced (Gunn et al., 1980; Little, 1971 and 1977). In addition to habitat reduction, the mirid fauna of the Delta has also been pressured by the use of insecticides for agricultural pests. In the past, insecticides were commonly applied to crops (especially cotton)

on a scheduled basis regardless of need, and the use of more than 10 applications in a single season was not uncommon. These insecticides may have reduced the number of mirid species in the Delta because of the proximity of many of the suitable mirid habitats to sprayed fields. Because of the importance of the Delta as an agricultural area, this study was initiated to investigate and understand more fully plant bug-host relationships and plant bug distribution in the Delta. This study also helps document the species composition of Miridae found in the Delta so that changes in the mirid fauna potentially can be detected.

Miridae listed here were collected from September 1981 through October 1982, and during May 1983, at the sample locations shown in Fig. 1. Miridae were taken by sweepnet from the main crops and by sweepnet and beating net from wild plants growing in or near the crops. Samples were taken at each location at least on a monthly basis, except for samples at Vicksburg and Port Gibson, Mississippi that were taken during May 1983. Additional specimens also were collected in black light traps located at Greenville, MS; Mound, LA; and West Memphis, AR. A few species of Miridae were collected in pitfall traps placed in a small wooded area near Stoneville, MS. Seven-hundred and eleven host-plant specimens were collected and are deposited at The Institute for Botanical Exploration, Botany Department, Mississippi State University, Mississippi State, MS.

One hundred and seven species of Miridae representing 7 subfamilies, 13 tribes, and 47 genera were collected in the study. All were identified by the second author; specimens are deposited at the Mississippi Entomological Museum, Entomology Department, Mississippi State University, and the U.S. National Museum of Natural History. The classification system used in the list follows that used by Wheeler et al. (1983). All apparent new state records are marked with an asterisk. Although five possibly new species were discovered, they are not included in the present work. They will be treated in future papers by the second author.

State, county, and plant host(s) (when available) are given for each species. Those species collected in a black light trap (BLT) are indicated. During some months only adults or only nymphs were collected on the host plant(s) listed. These months are preceded by (A) for adults only, or (N) for nymphs only. Authors and common names for the host plants are given in Table 1.

ACKNOWLEDGMENTS

We are grateful to Dr. Sidney McDaniel, Department of Biological Sciences, Mississippi State University, for his identification of the plant species collected in the study. This research was funded, in part, through Cooperative Agreement No. 58-7B30-1-300 between the Department of Entomology, Mississippi State University, and the Southern Field Crop Insect Management Laboratory, USDA-ARS.
